ABSTRACT

Objective(s): Pre-eclampsia is characterized by hypertension, dyslipidemia, and increased systemic inflammatory response and has been associated with an increased maternal risk of cardiovascular disease later in life. Endothelial dysfunction is thought to be a central pathogenic feature in pre-eclampsia on the basis of elevated adhesion molecules. The aim of this study was to determine the level of plasma serum level of vascular cell adhesion molecule-1 (sVCAM-1), intercellular adhesion molecule-1 (ICAM-1), high sensitive C-reactive protein (hs-CRP) in pre-eclampsia and to compare hs-CRP levels between normal pregnant women, mild and severe pre-eclampsia.

Materials and Methods: A cross-sectional study was conducted to determine the plasma concentrations of sVCAM-1, ICAM-1 and hs-CRP in peripheral blood obtained from normal pregnant women (n=40), mild pre-eclampsia (n=37) and severe pre-eclampsia (n=38). Concentrations of soluble adhesion molecule was determined with enzyme linked immunosorbent assay (ELISA).

Results: There were significant difference in the means serum hs-CRP between normal pregnant women and mild pre-eclamptic women (P<0.05). Serum concentration of hs-CRP, sVCAM-1(ng.ml) and sICAM-1(ng.ml) were significantly higher in severe pre-eclampsia (P<0.05) than normal pregnancy. There were also significant differences in hs-CRP, sICAM-1 and in sVCAM-1 levels between mild and severe pre-eclampsia (P<0.05). There was no difference in the mean plasma log sVCAM-1, sICAM-1 between normal pregnant women and mild pre-eclamptic women.

Conclusion: We have determined the serum concentration of soluble adhesion molecule ICAM-1, VCAM-1 and hsCRP in normal pregnancy and pre-eclampsia. Adhesion molecule is elevated in severe pre-eclampsia compared with normal pregnancy, hsCRP are elevated in severe pre-eclampsia compared with mild pre-eclampsia and normal pregnancy and may be useful in predicting the severity of pre-eclampsia.

Introduction

Several studies have suggested that concentrations of different soluble adhesion molecules may be useful markers of inflammation, and their concentrations have been found to be altered in conditions such as sepsis, acute coronary artery disease, renal allograft rejection, acute pancreatitis and rheumatoid arthritis (1).

Endothelial cell dysfunction is considered central to the pathophysiology of pre-eclampsia (2, 3) yet the mechanisms responsible for the development of endothelial dysfunction in this syndrome remain to be determined. Recent studies suggest that 'normal pregnancy is associated with changes in peripheral blood leukocytes similar to those observed in sepsis (4).

Pre-eclampsia (PE) develops in 4–5% of human pregnancies. It is characterized by an elevated blood pressure and proteinuria and develops after 20 weeks of gestational age. PE can result in

eclampsia when convulsions develop or manifest as the hemolysis, elevated liver enzymes and low platelet count (HELLP) syndrome. Several etiologies have been implicated in the development of pre-eclampsia. Some of them include abnormal trophoblast invasion of uterine blood vessels, immunological intolerance between fetoplacental and maternal tissues, maladaptation to the cardiovascular changes or dietary deficiencies and genetic abnormalities (5).

Adhesion molecules play a central role in the endothelial cells-leukocytes adherence and the subsequent migration of white blood cells into perivascular tissue.

Cellular forms of adhesion molecules mediate specific steps of leukocyte-endothelial cell interaction, and have been implicated in the pathophysiology of pre-eclampsia. Soluble forms of these molecules can be detected in plasma, and their concentrations are thought to reveal the degree of activation of a particular cell type. Increase in soluble forms of vascular cell adhesion molecule 1 (sVCAM-1) and soluble forms of intercellular adhesion molecule-1 (sICAM-1) indicate endothelial cell activation/dysfunction.

C-reactive protein (CRP) is a marker of systemic inflammation(6). It has been shown that CRP is elevated in women with PE (7).

High-sensitive (hs) CRP is a protein measured by either antibodies that are labeled with an enzyme (ELISA) or a fluorescent compound or antibody-coated polystyrene beads. Determination of hsCRP has been suggested to be more sensitive than conventional measurement of CRP and provides better sensitivity in confirmation of inflammation (8).

The patient’s serum samples stored at -20°C until assay. The concentrations of soluble adhesion molecules were measured using enzyme-linked immunoassays (Bender Med system, Human sVCAM-1, Bender Med System, Human sICAM-1, Austria). For all patients and normal pregnant women, serum hsCRP level was measured with immunoturbidimetric assay (Diagnostika kit, Germany).

The sensitivity of the assay for sICAM-1 was 2.17 ng/ml for sVCAM-1 was 0.63 ng/ml. The inter-and intra-assay coefficients of variation were 7.66% and 4.1% respectively for sICAM-1 and the inter-and intra-assay coefficients of variation were 5.6% and 3.5%, respectively for sVCAM-1.

The lowest limit of detection was 0.1 mg/l. The maximum inter-and intra-assay coefficients of variation for the range of concentrations evaluated were 3.5% for hsCRP.

Statistics

The t student-test was used for comparison of proportions. A level of $P < 0.05$ was regarded as statistically significant.

Results

This study included 40 normal pregnant women and 75 pregnant women with pre-eclampsia (37 Mild Preeclampsia and 38 Severe Pre-eclampsia). Table 1 lists the clinical characteristics of the three study groups.
Soluble vascular cell adhesion molecule-1 was detected in all specimens. There was no difference in the mean sVCAM-1 between normal pregnant women (97.1 ± 253) and mild pre-eclamptic women (1019 ± 288). Patients with severe pre-eclampsia had a significantly higher mean plasma level (1240 ± 553) than normal pregnant (6.7 ± 2 mg/l) and mild pre-eclamptic women (9.2 ± 7.1 mg/l) (P < 0.05).

In addition, hsCRP was detected in all specimens. There was a significant difference in the mean hsCRP between normal pregnant women and mild pre-eclamptic women (6.7 ± 2 mg/l vs. 9.2 ± 7.1 mg/l, P < 0.05). Patients with severe pre-eclampsia had a significantly higher mean plasma levels (12.8 ± 7.3 mg/l) than normal pregnant (6.7 ± 2 mg/l) and mild pre-eclamptic women (9.2 ± 7.1 mg/l) (P < 0.05).

Discussion

Pre-eclampsia is characterized by hypertension, dyslipidemia, and increased systemic inflammatory response and has been associated with an increased maternal risk of cardiovascular disease later in life (11).

In recent years, endothelial dysfunction has emerged as the leading phenomenon responsible for the clinical signs of the disorder (12, 13).

Pathogenesis, pre-eclampsia is thought to be resulted from generalized endothelial dysfunction (14). Recently, increased levels of cell adhesion molecules are believed to be indicators of endothelial dysfunction in pre-eclampsia (15).

Observational and experimental studies have demonstrated an association between inflammation and endothelial dysfunction (16, 17).

Previous studies of soluble adhesion molecules in the plasma of pre-eclamptic patients yielded conflicting results (18). Some studies reported an increase in sP-selectin, sE-selectin and sICAM-1, (19-21) while others reported no changes (22). In contrast, all of the studies have reported an increase in sVCAM-1 (19, 22-25).
Two studies reported an increased plasma concentration of sPECAM-1 in pre-eclampsia. (21, 26) 
(Lyall et al) (24) have reported that serum levels of VCAM-1 and E-selectin were not significantly different between normal and pre-eclamptic pregnancies. Chaiworapongsa et al (27) suggested that serum levels of ICAM-1 were no differences between normal and pre-eclamptic pregnancies.

Our findings indicate that severe pre-eclampsia, but not mild pre-eclampsia and normal pregnancy, was associated with an increase in sVCAM-1 and sICAM-1. Similar findings have been reported by other investigators (19, 21, 24, 28).

This observation is of considerable importance, because sVCAM-1 has a distinctive pattern of regulation and is rapidly induced by pro-atherosclerotic conditions (29). We interpret the elevation in sVCAM-1 in pre-eclampsia as evidence of endothelial cell activation/dysfunction and may be useful in predicting the severity of pre-eclampsia.

In one study, plasma sICAM-1 and sVCAM-1 were analyzed between weeks 22 and 29 of gestation in 1543 pregnant women and related to the outcome of pregnancy in a prospective longitudinal study. Plasma sICAM-1 and sVCAM-1 in uncomplicated pregnancies were normally distributed and varied over a small range. In contrast, out of 177 pregnancies with complications (with a prevalence of 11.5%), 97 (55%) had sICAM-1 or sVCAM-1 concentrations above the same cutoffs weeks before the onset of disease. Therefore, mid-gestation measurements of circulating sICAM-1 and sVCAM-1 have a high predictive value and may recognize up to 55% of pregnant women who will later develop a severe pregnancy-related complication (30).

Early enhanced activation of endothelial cells, platelets and leukocytes seem to be present in pre-eclamptic patients, especially in those who develop severe pre-eclampsia (31).

There is increasing evidence that pre-eclampsia is a systemic inflammatory disease (32). CRP is responsible for the clearance of membranes and nuclear (4, 7, 32) antigens and acts as a scavenger (33).

Some reports have shown that elevated CRP levels during first trimester of pregnancy are indicative of pre-eclampsia. (34) But another study reported that serum levels of CRP at 23-25 weeks of gestation were similar in pregnant women who subsequently developed pre-eclampsia and in women without complications of pregnancy (35).

Although normal pregnancy is associated with increased pro-inflammatory markers, it has been suggested that the cause of serum hsCRP elevation in the pre-eclamptic women may be a result of reduced plasma volume in these patients (32, 33).

The relationship of CRP levels and preeclampsia has already been studied and higher concentration of CRP has been reported during preeclampsia (7, 36). It has also been shown that women with a history of preeclampsia had increased CRP levels (37).

In our study, levels of hsCRP were found to be significantly higher in women with mild and severe pre-eclampsia than in normotensive women with similar chronological age.

(Belo et al) found significantly higher levels of CRP in preeclampsia, but statistical significance were lost after adjustment for maternal weight (38). Üstün et al showed that level of CRP to be significantly higher in women with mild and severe pre-eclampsia than in normal pregnant women with similar chronological age, gestational age, and body mass index (39).

Although inflammation may not be the exact cause of pre-eclampsia, it may enhance the pathology of the disorder in the presence of the anti-angiogenic factors (12).

Hwang HS et al showed that hsCRP levels were positively correlated to pregnancy duration in healthy women and could be used as a severity marker in women with severe PE (9).

In 2011 (Can M, et al) found that severe pre-eclampsia group hsCRP levels were significantly higher than mild pre-eclamptic and normotensive groups (40).

There are also few studies concerning CRP levels due to severity of pre-eclampsia (41). In these studies, it has been shown that CRP levels were positively related to the degree of blood pressure elevation. In our study, we found significantly higher levels of hsCRP in severe pre-eclampsia than mild pre-eclampsia.

Conclusion
We have determined the serum concentration of soluble adhesion molecule ICAM-1, VCAM-1 and hsCRP in normal pregnancy and pre-eclampsia. Adhesion molecules are elevated in severe pre-eclampsia compared with normal pregnancy, hsCRP is elevated in severe pre-eclampsia compared with mild pre-eclampsia and normal pregnancy and may be useful in predicting the severity of pre-eclampsia. The clinical validity of the monitoring of hsCRP needs to be established in further longitudinal studies.
